

45 proposals for reducing CO2 emissions and sustainable energy generation for the consultation of the Regional Energy Strategy Arnhem-Nijmegen Region on 23 September 2019.

[Urgenda Presents 40 Solutions for 25% CO2 Reduction](#)

The 40-point plan contains 40 measures to comply with the ruling in the Climate case: 25% CO2 reduction before the end of 2020. Together with more than 700 organizations, the 40-point plan was presented and handed over to the Dutch government in June 2019, 4 years after winning the Climate Case in The Hague. The 40 measures are a guide and show that it is possible to reduce 25% CO2 in the Netherlands before the end of 2020. All measures together are good for a reduction of 10 to 15 Mton CO2-eq.

01 - 100,000 rental houses energy neutral 0.2 Mton	21 - Spare transformers for sun & wind 0.4 Mton
02 - Fewer cows, no less profit 3.0 Mton	22 - Doubling of shrinkage of the pig sector 0.3 Mton
03 - Maximum speed on roads decrease 0.2 Mton	23 - Sun at School 0.2 Mton
04 - Scaling up national energy fight 0.2 Mton	24 - LED lighting in companies and greenhouses 1.0 Mton
05 - Switch off the lighting after working hours 0.3 Mton	25 - Other Ways to Travel coalition 1.0 Mton
06 - Network of semi-autonomous small vehicles 0.5 Mton	26 - Balancing heat installations companies 0.5 Mton
07 - Sustainable forest management 0.2 Mton	27 - Tires with a pressure of 0.2 Mton
08 - Link tenders to savings obligation of 0.4 Mton	28 - CO2 Performance ladder 1.0 Mton
09 - Retain 0.4 Mton	29 - Campaign for CV optimization households 0.4 Mton
10 - Green roofs 0.1 Mton	30 - MOT for buildings 0.1 Mton
11 - A day a week without meat 0.5 Mton	31 - City tax for a livable city 0.1 Mton
12 - Accelerated watering peat meadow 0.2 Mton	32 - Innovative Chemical Recycling Techniques 0.2 Mton
13 - Action plan for electric motors 2.0 Mton	33 - Doubling power energy cooperatives 0.1 Mton
14 - ISDE increase for small-scale heat 0.1 Mton	34 - Action plan from single to HR ++ glass 0.2 Mton
15 - Extra budget for home insulation 0.2 Mton	35 - Forests, trees and roadsides 0,1 Mton
16 - Stimulation collective solar systems 0.1 Mton	36 - Stopping recreational use of laughing gas 0.1 Mton
17 - Lease contracts for solar panels on a kWh basis 0.1 Mton	37 - More sustainable asphalt 0.1 Mton
18 - Always count solar panel in energy label 0.1 Mton	38 - More use of 0.1 Mton olive sand
19 - Regulation solar panels & remediation asbestos roof 0.1 Mton	39 - Government campaign "it is possible"! 0.5 Mton
20 - Solar panels on government buildings 0.1 Mton	40 - Innovations with potential 0.1 Mton

[Urgenda Solution Number 1](#)

01 - 100,000 rental houses energy neutral 0.2 Mton

This first measure results in a 100,000 (almost) energy-neutral homes with a (very) small energy bill, of which tenants benefit from day one. The housing corporations can pay that with the amount that they now pay the government because of the so-called landlord tax. This was a temporary tax measure that has never been stopped and will amount to 2 billion in the coming year. In addition to two improper taxes together, 4 billion, 4 months rent that the government skims. And then they complain that not enough is being done by corporations. It is time for a breath of fresh air, stop the temporary landlord levy, 6 years was enough.

[Urgenda Solution Number 2](#)

02 - Fewer cows, no less profit 3.0 Mton

The second measure is shrinking and changes in livestock which results in a reduction of 3 megatons of CO₂ eq per year. After the closure of the coal-fired power stations, that is one of the largest measures that can still be taken for the climate.

It also improves biodiversity. However, it is not the intention to let the farmers pay the bill again, because they have been given measure after measure in recent years.

Yet there is a good reason to have another look at the number of cows, because if we do not do that ourselves, then Brussels will probably force us to take far-reaching measures. The Netherlands emits too much nitrogen and still produces a relatively large amount of manure, both of which ensure that we do not meet the EU standards that the Netherlands has signed for.

Nitrogen, of which dairy farming is the largest source, has negative effects on nature reserves, insects, soil life and health. To strongly limit EU standards and the negative effects in 2030, we will certainly have to reduce by 30%: less (artificial) manure, less concentrate and therefore fewer cows or much less milk per cow. To prevent a repetition of 2016, when 160,000 cows suddenly had to go to the slaughter because we did not meet the EU standards for phosphate, we can now take matters into our own hands and make changes in 1.5 years, without the farmer receiving less income.

Part of the solution can lie in having cows give less milk. Cows now give an extremely high amount of milk, which can be reduced by 15 to 20% through concentrate reduction and fertilizer reduction. The remaining 10% reduction will then have to come from a shrinking of the herd and the choice of other cow breeds. We now know that slightly fewer cows and a better balance between the number of cows and the amount of land not only leads to lower produces, but also to lower costs. On balance, the farmer does not have to suffer loss. This offers prospects for more dairy farmers. If we want to make such a big change within two years, then we will have to help farmers, with knowledge and budget to compensate for the loss of income. There are plenty of good examples that deserve good follow-up. A lot of money has now been reserved for tackling the nitrogen problem, 2.2 billion euros alone for improving the quality of nature. Let us use that for the switch to sustainable agriculture.

[Urgenda Solution Number 3](#)

03 - Maximum speed on roads decrease 0.2 Mton

A simple but powerful measure can be to lower the maximum speed. It is also a measure that the government can take relatively quickly, at very low costs. It is up to the government how difficult or easy they want to make it for themselves.

Simply going back to 100/120 will result in a 0.2 Mton (megaton) CO2 emission reduction. Slowing down even more can yield 1.2 Mton.

[Urgenda Solution Number 4](#)

04 - Scaling up national energy fight 0.2 Mton

The government can encourage healthcare institutions to participate in the 'Energy Saving Competition' or give them a voucher to let an expert walk through a healthcare institution for a day to take all simple measures that can be taken without much money and energy. That quickly leads to 10-15% savings in a winter season. The advantage of an Energy Saving Competition is that the behavioral change itself is chosen and is experienced as positive and fun and not as an imposed measure.

[Urgenda Solution Number 5](#)

05 - Switch off the lighting after working hours 0.3 Mton

Shops and offices still too often leave unnecessary lights on after working hours. Often the lighting is switched on unnecessarily throughout the weekend. It was previously calculated that 536 million kWh of electricity can be saved by switching off unnecessary lighting outside of operating time. That saves 0.36 Mton per year in CO2 emissions. A timer, sweep switch, motion detection or simply making someone responsible for it, works wonders and is easily earned back.

[Urgenda Solution Number 6](#)

06 - Network of semi-autonomous small vehicles 0.5 Mton

There are a lot of delivery vans that together emit 5.3 Mton per year and form a very inefficient form of distribution. Part of these emissions can be eliminated by driving with semi-autonomous electric vehicles, running at the speed of a walker to jogger (5-8 km / h) and the size of a low ice cream cart (80-100 cm wide, up to max. 2 m long, max. 750 kg) drive on the right in the countryside, on holiday parks and industrial sites and transport things that are not in a hurry. The vehicle is full of sensors and learns to drive fixed routes. If there is an unexpected obstacle, then it stops and someone looks at it remotely to see how the cart can get around it.

[Urgenda Solution Number 7](#)

07 - Sustainable forest management 0.2 Mton

Trees and forests capture a lot of CO₂. Trees and forests are also extremely important for biodiversity. It is therefore important that we treat our forests and trees with care and strive for natural forests with a varied uprising of native trees and shrubs.

Yet many trees are cut down. Sometimes that is not a problem, for example when cutting is done because trees are sick, to come to natural forests or to preserve other nature.

In recent years, however, a lot of wood has disappeared in biomass plants and bark clearing has returned as a control measure for harvesting and growing wood. A piece of forest of about 0.5-2 hectares is cut bare, the litter layer removed and replanted, resulting in a great loss of recorded CO₂ and biodiversity. More sustainable forest management benefits biodiversity and can result in a saving of 175,000 tons of CO₂.

[Urgenda Solution Number 8](#)

08 - Link tenders to savings obligation of 0.4 Mton

The Environmental Management Act has had an energy saving obligation since 1993. This energy saving obligation is defined as the obligation for organizations to take all energy saving measures that pay for themselves within five years or less.

Not all companies and institutions comply with this legal obligation. Those who do so should be rewarded with assignments from the government.

The first Energy Agreement had an energy saving target for 2020 of 100 Petajoules. The National Energy Survey of 2017 (NEV 2017) showed that this energy saving was still 25 Petajoules behind its goal. This 25 Petajoule extra energy saving is equivalent to approximately 1.5 megatons of CO₂ reduction. Part of this gap is caused by the non-compliance with the energy-saving obligation for companies.

[Urgenda Solution Number 9](#)

09 - Retain 0.4 Mton

Fortunately, the government has already decided that netting will not be stopped in 2020 or 2021, but will be continued until 2023 and then gradually phased out. That's great, because it provides certainty and makes people dare to invest again. Then the market for solar energy can grow even faster. The growth of Solar PV in 2018 was more than 1.4 GWp. In 2019, it is estimated that 2 GWp will be installed. If this continues in 2020, we will go to 6.3 GWp at the end of 2019 and more than 9 GWp at the end of 2020 (estimate Dutch New Energy

Research), higher than the government's goal.

If netting continues, then 7 GWp in 2020 should also be easily achievable. So 1 GW extra sun power compared to existing goals. This leads to an additional reduction of approximately 0.4 Mton. This is calculated with the Energy Transition Model.

A scenario with 7 GWp sun on the roof is compared to a scenario with 6 GWp sun on the roof. This extra GWp results in a 0.4 Mton reduction in CO₂ emissions (470 g / kWh generated with the extra sun). In this calculation we have assumed only changes in sun on roofs. If the rest of

the energy system also changes, this also has consequences for the impact of extra sun on roofs. For example, if the extra Solar PV on roofs causes a coal-fired power station (600 - 1050 g / kWh) to run less, the additional reduction can amount to 0.9 Mton.

[Urgenda Solution Number 10](#)

10 - Green roofs 0.1 Mton

Much has already been calculated on green roofs: cleaner air, more insects, cooling, less painkiller use and many more benefits. But it also delivers CO2 savings. The Geodienst of the University of Groningen calculated that the 9 largest cities already have more than 40 km of flat roof surface. If we put sedum on it, it saves 0.1 Mton CO2. If we also opt for natural roofs or a combination with solar panels, the savings will increase.

[Urgenda Solution Number 11](#)

11 - A day a week without meat 0.5 Mton

If all Dutch people do not eat meat one day a week, Dutch CO2 emissions can be reduced by 0.5 Mton per year. No meat three days a week is in line with the guidelines for healthy food and the Schijf van Vijf and saves no less than 1.5 Mton / year. Our Western meat consumption has a major negative impact on climate, environment, health, biodiversity and on local communities in soy producing countries. This is precisely the reason why large institutions such as

the United Nations, the Netherlands Nutrition Center and RIVM have been advocating lower meat consumption for some time. This is also the reason why 30 organizations - from Animal Protection, Doctors & Lifestyle to Oxfam Novib - are now asking the government to introduce measures as quickly as possible to help consumers opt more often for vegetable meat substitutes: a financial incentive for meat that is set to ensure that the lower incomes are not limited more and that the proceeds of the incentive are used to help farmers become more sustainable. Research shows that such an incentive will save millions of euros in health care.

[Urgenda Solution Number 12](#)

12 - Accelerated watering peat meadow 0.2 Mton

By raising the groundwater level in peat areas and creating more nature, the Cabinet can save 0.2 Mton CO2 by the end of 2020. The Cabinet's plans for 2030 to raise the water level in peat areas can be implemented at an accelerated rate. In the coming year, it is already possible to get started in the current nature areas with watering the peat, and new areas can be purchased more quickly.

This CO2 reduction measure is relatively cheap and has a major additional advantage: in the short term, more habitat will be created for many animal species that are currently seriously deteriorating. This way, climate and nature objectives are tackled integrally.

yield a lot of extra savings. A concrete action plan for electric motors, which also includes magnet couplings, must be able to deliver at least 2 Mton CO2 savings by the end of 2020

[Urgenda Solution Number 13](#)

13 - Action plan for electric motors 2.0 Mton

Electric motors account for 62% of industrial electricity consumption. Energy Research Center (ECN now part of TNO) calculated here a realistic saving of 3.78 Mton CO2 through a system approach (combination of better engines, better adjustment, speed and frequency controls, etc.) for the industrial and services sector.

ECN does not yet take into account the potential of contactless magnetic couplings: a promising innovation in electric motors that can

subsidy was oversubscribed last year. There is a lot of interest sustainable heat, in combination with a recruitment campaign. Double this pot for heat pumps and solar boilers next year and combine this in it. It helps people to take steps to make their home energy neutral. with much more public information.

[Urgenda Solution Number 14](#)

14 - ISDE increase for small-scale heat 0.1 Mton

The Investment Subsidy for Sustainable Energy (ISDE scheme) for small-scale sustainable heat provides a contribution to both individuals and business users when purchasing heat pumps, solar boilers, biomass boilers and pellet stoves. We would like this subsidy to continue without the biomass boiler and pellet stoves options.

Companies make their business premises more sustainable. There is more room with this scheme to realize relatively cost-effective

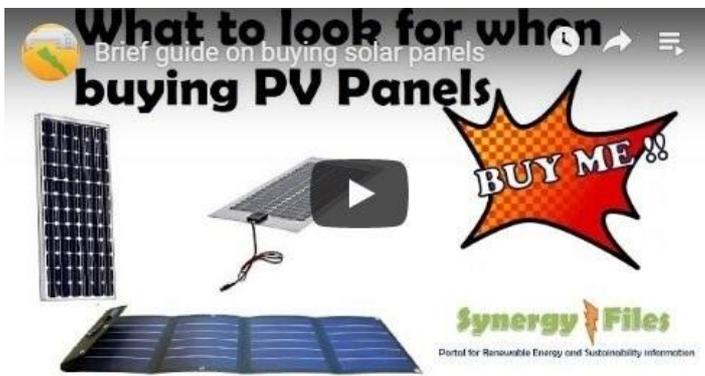

[Urgenda Solution Number 15](#)

15 - Extra budget for home insulation 0.2 Mton

Home insulation is a relatively cost-effective way to save CO2 in the built environment. Previous schemes such as the SEEH were also used well and were quickly "empty".

Reopening a scheme such as the SEEH, including a budget of € 100 million for 2019/2020, can lead to more insulation and 0.2 Mton extra CO2 savings. Here too an extra recruitment campaign would help to actually achieve the intended acceleration.

[Urgenda Solution Number 16](#)

16 - Stimulation collective solar systems 0.1 Mton

Housing corporations, private landlords and VVEs also want to lay solar panels on their roofs. That is too complicated for them with the current regulations such as the so-called "zip code regime".

Also in the EU it has been explicitly stated that citizens in stacked construction should have the same access to solar energy as people in a land-bound home ("winter package").

For both reasons and to reduce CO2 emissions more quickly, it would therefore be good to accelerate solar energy on collective roofs through a temporary feed-in subsidy of € 0.10 per kWh for a period of two years. The "contracting party" is the housing association, landlord or VVE. They can divide the income fairly among the residents and settle (part of) the costs through the service costs and / or the rent. Until the end of 2020 this measure could lead to MWP of additional installed capacity and in 2020 an additional CO2 reduction compared to 1990 of at least 0.1 Mton.

[Urgenda Solution Number 17](#)

17 - Lease contracts for solar panels on a kWh basis 0.1 Mton

Owners of large roofs often do not want to purchase and maintain an installation with solar panels on their roof, but do want to be "unburdened" by another party who lays the panels on their roof and then leases the person who owns the roof. Now those lease contracts cannot be concluded based on the generated kWh, but must be based on a fixed amount per year. This is because the Environmental Tax Act states that there is no need to pay any energy tax if the generation is done on the roof "for own account and risk of the end user".

With a lease construction, the leasing company has (part of) the bill and risk and is therefore not allowed to settle per kWh. This creates risks for developers, so that much larger projects do not take place. Enabling lease contracts for solar panels to be concluded on a kWh basis and releasing the "for own account and risk requirement" in the Environmental Tax Act (or via temporary policy rules) makes lease contracts fairer, cheaper and more transparent. Until the end of 2020 this measure could lead to an additional 500 MWP of installed capacity and in 2020 an additional CO2 reduction compared to 1990 of at least 0.1 Mton.

[Urgenda Solution Number 18](#)

18 - Always count solar panel in energy label 0.1 Mton

When a roof is used by a party other than the building owner for a solar project the PV system does not count towards the energy label of the building. This makes building owners reluctant to make roof space available: they would rather develop their own project on it at a later stage. This causes a net delay. If the solar panels on a roof can always count towards the energy label, whoever laid them down on that roof, this could lead to an additional 500 MWP of installed capacity until the end of 2020 and in 2020 an additional CO2

reduction compared to 1990 of at least 1990.1 Mton.

"asbestos off, sun on". For example, by expanding the SDE + with this option. It is also expected that such a system could lead to 500 MWp installed capacity up and until 2020 and causes extra CO2 reduction compared to 1990 of at least 0.1 megatons in 2020. The NVDE made a [comprehensive note](#) on this.

[Urgenda Solution Number 19](#)

19 - Regulation solar panels & remediation asbestos roof 0.1 Mton

Continuation of arrangement combination solar panels with asbestos roofs. The government wants all asbestos roofs to have been removed in 2024, But recently the Dutch Senate has not approved legislation to regulate it.

Perhaps the government can still make it attractive for Dutch citizens to remove the asbestos roofs, by provincial regulations such as

These PV projects can of course use various incentives (offset, SDE, PCR etc.), but that should not be a prerequisite to get started. In 2020 this additional installed capacity can lead to an additional reduction in CO2 emissions compared to 1990 by at least 0.1 megatons. The NVDE made a [comprehensive note](#) on this.

[Urgenda Solution Number 20](#)

20 - Solar panels on government buildings 0.1 Mton

The government, national, regional and local, has many roofs that are not all filled with solar panels and / or green roofs. Setting a good example, if you require a lot of your citizens, is always wise. Many roofs of public buildings offer a good opportunity for solar projects: they can do it themselves or provide the roof to local energy cooperatives. A government that takes the energy transition seriously, can easily decide to fill up its own suitable roofs within the next 1.5 years with solar panels.

In the jargon: The rule is the standard requirement of n-1 or n-2 redundancy when connecting renewable projects. For a lot of wind and PV projects, it is not crucial that their network availability is 99.99%; 99%, or n-0 would also suffice. Rapid adaptation of this requirement in the regulations would directly lead to increased implementation rate of available new solar and wind projects. This is expected until mid-2020 to give 3 GWp of additional connecting opportunities.

[Urgenda Solution Number 21](#)

21 - Spare transformers for sun & wind 0.4 Mton

By using spare transformers (thus releasing the N-1 redundancy requirement) to solar and wind projects, which seem to need grid reinforcement now, can be connected to the grid sooner. In extreme cases, the solar or wind project is disconnected momentarily.

The supply to third parties is not reduced. Currently legislation requires that there is significant spare capacity in the grid so that there is never a moment without power.

sector is inevitable due to the negative impact on climate, environment, animal welfare, deforestation and humandestroyed.

health. According to forecasts, 70% of all pig farmers will stop between now and 2030. At the same time, it is expected that the number of pigs will only shrink by 10% in 2030. The remaining farms are expected to be many times larger than they are now. In line with the LNV vision for circular agriculture and in the context of the nitrogen deposition, it is wise to shrink the number of pigs with the number of farmers. This would amount to 7 to 8 million less pigs and more than 1.5 Mton CO2 savings in 2030.

[Urgenda Solution Number 22](#)

22 - Doubling of shrinkage of the pig sector 0.3 Mton

The government is allocating 120 million euros for a warm clean-up of the pig sector between now and 2023. According to the PBL, this scheme will lead to a reduction of 5% and a saving of 0.15 Mton CO2. But with additional measures and a doubling of the budget, at least 0.3 CO2 can be saved before the end of 2020. For example, the government can achieve a substantial shrinking of the pig population by helping farmers who have no successor (62%) with a quitting scheme, whereby the released pig rights are

from children to parents and to the neighborhood around the school.

For schools that do not know how to get started, there is help and for school boards that are short of cash, a loan is available. A personal letter from Prime Minister Rutte to all 1,260 school boards can help with the acceleration, because many schools do not yet know this program.

[Urgenda Solution Number 23](#)

23 - Sun at School 0.2 Mton

Saving energy and solar panels reduce CO2 emissions and are the stepping stone to further sustainable measures for the school building. In combination with education about sustainability for the children, this contributes to a new conscious generation. That is the basic idea behind this measure.

A measure that pays off, because the radiation effect of solar panels in sustainable schools is great: the green awareness is spreading

[Urgenda Solution Number 24](#)

24 - LED lighting in companies and greenhouses 1.0 Mton

The House of Representatives passed a motion by a large majority to oblige companies to use LED lighting only by 1 July 2020 at the latest. By accelerating the implementation of this motion and making LED lighting mandatory as of January 1, the government can save 0.9 Mton CO2 by the end of 2020. Help for growers who want to switch to LED in the form of a loan will lead to even more in 2020 once 0.1 Mton saving. The purchase of LED lighting pays for itself through a lower energy bill and can therefore count on broad support.

[Urgenda Solution Number 25](#)

25 - Different Ways to Travel coalition 1.0 Mton

CO2 emissions in the Netherlands from commuting and business traffic by car amounts to no less than 8.8 Mton (2016). Dozens of large companies with nearly 300,000 employees have joined forces in the Different Ways to Travel coalition. They want to encourage more sustainable travel and thereby reduce their CO2 emissions, among other things. In a report from March 2018, CE Delft has calculated the effects on emissions of various measures.

A number of these measures can also lead to a substantial reduction in emissions in 2019 and 2020. The following three measures would result in nearly 3 Mton fewer emissions in the longer term. 1 Mton should be possible in the short term of 1.5 years:

- Behavioral campaigns
- Reduced fee 0.19 / km for car use, for everyone
- Reimbursement for bicycle kilometers of 0.19 / km

[Urgenda Solution Number 26](#)

26 - Balancing heat installations companies 0.5 Mton

For the proper functioning of a climate installation it is important that the air quantities in an installation are brought into line with the design values. In addition, proper water-side adjustment is also very important in all kinds of heating installations to make the installation work efficiently. Poorly tuned devices use too much energy and cause unnecessary CO2 emissions. The technical potential for utility construction is between 20 and 30 Petajoules.

For the next 1.5 years, the savings could amount to 12 to 16 Petajoules, rounded down this leads to 0.5 Mton CO2 reduction.

[Urgenda Solution Number 27](#)

27 - Tires with a pressure of 0.2 Mton

If half of the drivers start inflating their tires correctly every two months, this will save 0.2 Mton CO2 per year. It also saves 100 euros per year per car (or 400 million euros in total!). Most people don't know that they can save 100 euros by pumping up their tires for 10 seconds every now and then.

Better communication about this is important. 60% of all cars drive with low tire pressure. By placing 2,500 smart tire pumps at

companies, gas stations and supermarkets and by providing clear explanations, motorists will be able to adjust their tires better and more often.

A project where, for example, people who are at a distance from the labor market or sellers of homeless newspapers can earn something by operating the tire pump could be a nice extra source of income for them. If people save 100 euros a year, then a couple of euros for the "tire tensioner" can get rid of it? The regular air pumps at gas stations often do not work well enough. The new tire pump is easy to use with the touchscreen and helps with smart software even by typing in the license plate number directly to find the correct tire pressure. Tougher tires not only generate money and CO2 benefits, they are also safer and lead to less wear and tear, resulting in fewer microplastics ending up in the environment, and reducing traffic noise.

[Urgenda Solution Number 28](#)

28 - CO2 Performance ladder 1.0 Mton

Measure 28 has been drawn up with the Foundation for Climate Friendly Entrepreneurship and Public Procurement (SKAO). For saving 1.0 Mton CO₂, measure 28 proposes that companies, organizations and governments with a medium to large size should introduce a professional CO₂ management system in 2020. According to a first estimate of the proposed measure for the mandatory introduction of a CO₂ management system, this means a doubling of this saving potential.

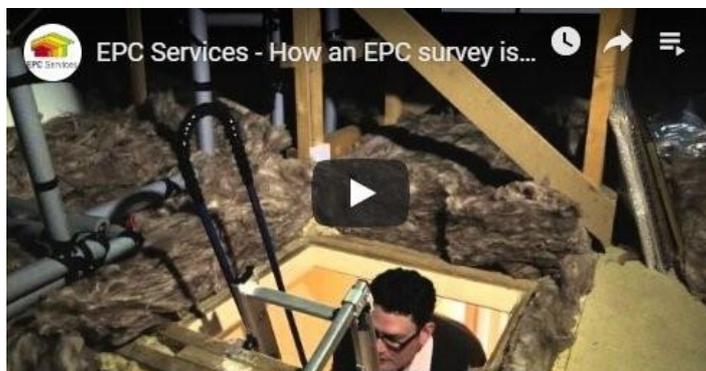

This corresponds to approximately 1 Mton extra CO₂ reduction. The proposal is in line with the Environmental Management Act (Wet Milieubeheer). It states that all companies that consume 50,000 kWh of electricity or 25,000 m³ of natural gas (equivalent) per year are obliged to report their energy-saving measures. Companies that consume 200,000 kWh of electricity or 75,000 m³ of natural gas equivalents on fuels per year are obliged to do their own research.

[Urgenda Solution Number 29](#)

29 - Campaign for CV optimization households 0.4 Mton

If Many central heating boilers from private individuals are not properly adjusted on the water side and are therefore not running efficiently. A national campaign to encourage people to have their installation checked and to train installers to do this really well are part of this measure. Explaining how much cost people can save with better adjustment is very important. This measure is quickly earned back. The technical saving potential in the entire housing stock is somewhere around 30 to 35 Petajoules. A saving of 0.4 Mton could be achieved for the next 1.5 years if a third of people with a central heating boiler has their system adjusted better.

[Urgenda Solution Number 30](#)

30 - MOT for buildings 0.1 Mton

A periodic check on the actual energy performance of buildings, a kind of MOT test or Energy Performance Inspection (EPC), would save in the next 12 to 18 months in the magnitude of 0.1 to 0.2 Mton (5 to 8 Petajoule). An EPK can be implemented quickly and easily, without changing legislation. The EPK would relate to all establishments under the Activities Decree 2.15 regime and / or all buildings with a use surface of more than 500 m².

An EPK is needed to close a gap in current policy, focusing in particular on theoretical average performance of individual energysaving measures, which rarely show this performance in practice.

[Urgenda Solution Number 31](#)

31 - City tax for a livable city 0.1 Mton

If In order to make the city of London livable again within the ring, the Congestion Charge was introduced in 2003. This area is still one of the largest in the world where this system exists. This is a toll system whereby cars in the central area within the ring - the Congestion Charge Zone - have to pay an amount per day between 7 a.m. and 6 p.m. (this was 10 to 12 pounds).

The toll is charged via a license plate recognition system. Electric and very clean vehicles pay less than dirty diesel cars and buses.

This has been further refined, since 2015 there are no more exceptions and only fully electric vehicles are spared. Now people are also going to favor sharing, so that people are alone in a car less. According to the Amsterdam Climate Neutral Route 2050 (January 2019), emissions from transport are 360 kilotons per year, ie 0.36 Mton. A test in five cities within the ring (with a scan on all exits) should be possible with financial support from the government. Five Dutch cities that together have a conservative estimated 1.5 Mton in transport emissions. Suppose that the car kilometers, just like in London, decrease by 11%, then - very conservatively - it should be possible to reduce 0.1 Mton CO₂.

[Urgenda Solution Number 32](#)

32 - Innovative Chemical Recycling Techniques 0.2 Mton

Chemical recycling could in the short term be a good addition to mechanical recycling for plastic waste. In both the new Coalition Agreement and in the transition agendas for the circular economy, chemical recycling is seen as an important solution for making the plastic chain more sustainable.

On behalf of the Ministry of Economic Affairs, CE Delft has calculated that a saving of 0.2 Mton is already possible in 2020.

The government can make this technique if they were to:

- include monomer chemical recycling in the plastic recycling targets;
- include chemical recycling feedstock with a factor of around 50% in the plastic recycling targets;
- make a subsidy for investments in chemical recycling possible under the new SDE ++ subsidy scheme;
- increase the recycling targets for plastic, including in the packaging framework agreement;
- give chemical recycling a better place in the national waste plan (LAP3) in terms of recycling quality. 240,000 tons of suitable material from households

[Urgenda Solution Number 33](#)

33 - Doubling power energy cooperatives 0.1 Mton

Strengthen the zip code scheme and double sustainable energy projects. The government has given the Regulation for a Reduced Tariff (RVT) - the postal code arrangement in the popular language as an instrument to energy cooperatives to help realize (local) sustainable energy projects.

This tax arrangement is based on supplying energy without energy tax and the VAT on it to members of the cooperative. It is a beautiful and successful instrument to let citizens benefit from the energy transition and to motivate them for it. If the current trend continues, 74.5 MWp will double in 2014 to 142.7 MWp in 2019 and grow to 280 MWp in 2020. Corporations expect 250 MWp extra growth if there is a fixed fee for postal code boxes, which leads to an additional reduction of 0.1 Mton CO2 emissions in 2020. For the longer term, sustained growth from the bottom-up movement can be helped by two measures.

[Urgenda Solution Number 34](#)

34 - Action plan from single to HR ++ glass 0.2 Mton

In the Netherlands, more than 1 million homes have single glass, an average of 20 m2 per home. Replacing this 20 m2 with HR ++ glass costs almost 3,200 euros.

That is a major investment for citizens, but they save 460 euros a year in energy costs, so it is recovered in 7 years. With a special ISDE subsidy for replacing single glass over the next 1.5 years, 250,000 households could be tempted to make the move.

Measure 34 proposes to offer 1,000 euros per household through an ISDE subsidy, so that the payback period of the citizen becomes around 5 years. Saving On average, the saving of replacing single glass with HR ++ glass is 800 kilos of CO2 / year (source: MilieuCentraal) per home. With 250,000 households, that means a profit of 0.2 Mton. Cost Tackling 25% of the houses in 1.5 years amounts to 250,000 times € 1000 subsidy via ISDE is 250 million euros.

[Urgenda Solution Number 35](#)

35 - Forests, trees and roadsides 0,1 Mton

If Where industry is looking for modern technologies to capture CO2, the very best and cheapest technology has already been invented: trees. In particular, forests capture a lot of CO2 in the soil and in the trees themselves.

But individual trees also absorb CO2, provide cooling and help with water storage. More trees and more green space is therefore already included in the Climate Agreement. Measure 35 is threefold: speeding up the plans for more forest and trees, and better use of verges. This measure is supplementary to measure 7: more sustainable forest management of existing forests.

[Urgenda Solution Number 36](#)

36 - Stopping recreational use of laughing gas 0.1 Mton

Laughing gas (N₂O, nitrous oxide) is a very strong greenhouse gas: 1 kilo of laughing gas has the same effect as 265 kilos of CO₂ according to the latest insights (see the adjacent table and also Milieu Centraal).

It is released, among other things, from soil that has been fertilized with artificial fertilizer or animal manure. It is also used as anesthetic gas in anesthetics and in engines to increase engine power.

The laughing gas patterns and balloons that are used "in the recreational atmosphere" are in fact lying en masse on the ground in cities, on festival grounds and in all kinds of other places where people come together to party. However, more and more car accidents seem to be associated with the use of laughing gas. And that laughing gas is a strong greenhouse gas is very clear. The increase in laughing gas imports appears to be almost entirely due to "recreational use." That is 500 tons of laughing gas extra and that equals 0.1 Mton extra CO₂ eq emissions. The government can reduce 0.1 Mton emissions year after year if this form of laughing gas use is reduced.

[Urgenda Solution Number 37](#)

37 - More sustainable asphalt 0.1 Mton

The Netherlands has one of the most densely branched road networks in the world. Of this network there are around 130,000 kilometers of paved road. As the largest client in the civil engineering, road and hydraulic engineering sectors, the government can set conditions for more sustainable asphalt in tenders.

Realistic in 2020 is a saving of 0.1 Mton CO₂ through the construction of cycle paths of biobased asphalt, more use of asphalt made at a

lower temperature, more reuse of raw materials from old asphalt and measures to extend the life of asphalt. This measure was written in collaboration with BAM (points 1 to 3) and Miscancell (point 4).

[Urgenda Solution Number 38](#)

38 - More use of 0.1 Mton olive sand

If CO₂ Open (climatecleanup.org) is the window on the emerging sector of natural climate solutions such as seaweed farming, forests and soil improvement.

To the 40-point plan, we are adding a solution with great potential that can clean up a lot of CO₂ by 2020: the use of olivine sand. Olivine cleans up CO₂ through natural weathering, in which it reacts with CO₂ and the carbon is captured for a very long time.

Olivine is a mineral that is common in the world (at least a quarter of the earth's crust). By grinding it to sand, the natural weathering reaction is accelerated. Taylor et al. (2016) estimate that this method can potentially reduce CO₂ concentration by 30 to 300 ppm (the current CO₂ concentration is around 415 ppm). In the Drawdown study (Paul Hawken, 2018) olivine is mentioned as a promising climate solution.

[Urgenda Solution Number 39](#)

39 - Government campaign "it is possible"! 0.5 Mton

If in the short term, most can be achieved with energy saving. This can be done in many ways, with households as well as with offices, farmers and industry. In the past year, the population of the Netherlands has gotten the idea that "the energy transition" is a large, stubborn, money-consuming monster that does not produce anything. It is time for a good multimedia campaign: "it is possible", which shows that saving energy or choosing other sustainable solutions is fun, can generate money and often also leads to more health, quality of life,

biodiversity and wonder. How can we get and interest a large part of the population? Tell the stories about the great solutions and what they deliver. Show what is already possible and how nice it is. Show young people who find more sustainable living very normal. Such a campaign can take many forms, of course, but we will provide a series of ideas for inspiration.

- Surprise Dutch people with a saving package
- Promote the CO2 Open - www.climatecleanup.org
- Promote the CO2 Calculator
- Start the E-team

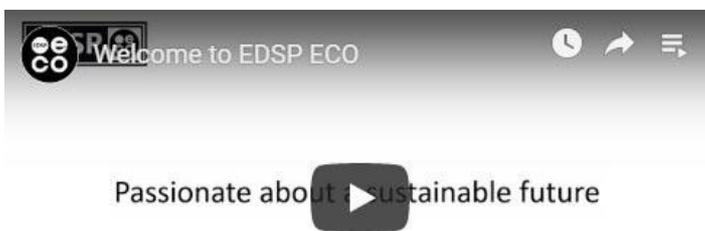

[Urgenda Solution Number 40](#)

40 - Innovations with potential 0.1 Mton

There are many innovations that want to scale up quickly. In the short term of 1.5 years, the effect on CO2 reduction is still relatively small, but before 2030 they can make a much greater contribution. To speed up the transition, it would help if those innovations come to fruition faster. We mention a few here, which together lead to 0.1 Mton even before the end of 2020, but certainly have a lot of potential afterwards.

- More durable paper
- paper process without water
- extra energy saving in transition phase
- Tocado, energy from tides
- Wiras the more efficient rail change
- Building with hemp
- Deep geothermal energy

[EDSP - Climate Solutions](#)

EDSP ECO is a non-profit organization and we view climate change as one of the biggest challenges of our times and aim for a fast transition towards a sustainable society using only renewable energy. We develop innovative, durable and sustainable technologies for this transition and promote the ideas of organizations we work with like the 40 solutions provided by

[Urgenda](#). EDSP provides platforms and executes multiple projects to support organizations who fight climate change like the [Mobilisation for the Environment](#) (MOB) and other organizations who confront

government & dirty company policies not in line with the changes required to save the planet. The 45 climate solutions provided below are supported by nearly a thousand organizations worldwide to prevent a dangerous climate change level.

First Solution - Stop Providing Subsidies for Fossil Fuel
 2019-04-09-european-commission-report-state-of-energy-union

It's unbelievable and most likely criminal but every year massive subsidies are given to the fossil fuel industry. We should invest those subsidies in wind mills, solar power and innovative solutions instead. Stop handing out our money to companies who wreck our environment. Politicians who promote subsidies for fossil fuel companies should be persecuted. ODI research reveals that G20 governments have broken their climate promises, spending \$444 billion each year to support fossil fuel production.

EU Commission Report 2019 "(...) A phase-out of environmentally harmful fossil fuel subsidies is necessary to achieve an efficient and effective Energy Union, as recognized by EU commitments in the G20 framework. Between 2008 and 2016, fossil fuel subsidies did not decrease. These subsidies are estimated to be worth EUR 55 billion in 2016, implying that EU and national policies are not yet sufficient to phase them out (...)" Read more: odi.org/empty-promises

Second Solution - Stop Handing Out Subsidies for Burning Woody Biomass
 Flinders University

By including bioenergy in renewable energy targets, the EU is promoting direct and indirect subsidies for it, claiming that it is a sustainable alternative to fossil fuels. Every year billions of euro's in renewable energy subsidies paid out of a surcharge on our electricity bills – go to power stations burning wood. This is money which should go to genuinely low-carbon renewables such as wind, wave and solar power.

Third Solution - Only Invest Our Money in Clean & Sustainable Solutions & Innovation

2018-12-17-european-environment-agency-report-renewable-energy

We should invest the massive amount of subsidies currently given to fossil fuel and biomass burning plants to sustainable solutions as wind and solar power and innovative solutions. This won't be achieved by asking the politicians politely as they have promised change for over a decade without the promised outcome. We will have to hold them accountable as soon as possible and jail them for the disaster which they are causing by stealing our taxes and giving it to the owners and shareholders of dirty billion dollar companies.

EU Environment Agency Report 2018 ""(...) the largest amounts of gross avoided GHG emissions were attributable to onshore wind energy (137 MtCO2), solar PV energy (73 MtCO2) and heat from solid biomass (37 MtCO2). Onshore wind and solar PV energy are also the most significant contributors to avoided fossil fuel consumption and avoided primary energy consumption. In contrast, heat from solid biomass increased primary energy consumption by 3.5 Mtoe. The use of solid biomass for electricity and heating leads to a reduction in GHG emissions [be aware, this claim is under discussion in an ongoing European court case -red] and fossil fuel consumption, but it drives up primary energy consumption (...)"

Fourth Solution - Use Wind & Solar Power to Generate Hydrogen & Convert Natural Gas Infra

2019-05-03-foresight-hydrogen-northern-netherlands-is-read y

According to The Scientific American, Orsted, Denmark's largest power company, announced it is planning to convert electricity from its wind farms into hydrogen fuel.

They plan to achieve this by using electricity from wind farms to power electrolysis plants. These are capable of splitting water into oxygen and hydrogen that can be used as energy.

The resulting hydrogen would be stored in a natural gas distribution system and used when there's a shortage of wind and sunlight powering the wind farms. Currently, there are 45 projects in Europe working on making power-to-gas conversion technologies more efficient and affordable. According to a study published in February in the journal Nature Energy, the cost of splitting water has lowered by 40 percent, suggesting the technology could become more accessible in the near future. According to Dutch energy consultancy, Navigant, using gas storage networks to support the European power system could help European consumers save up to \$156 billion.

Fifth Solution - Only Burn Natural Gas Whiles Investing Every RED Penny in Sustainability

2019-04-09-european-commission-report-state-of-energy-union

While investing every cent of subsidie we can spare into real sustainable solutions like wind and solar power and innovation we should end the burning of biomass, coal and oil and only use natural gas as non-renewable fuel source. The latest European Commission State of the Energy Report stated the European Commission has facilitated several rounds of trilateral talks between Ukraine and the Russian Federation aimed at ensuring the uninterrupted transit of

natural gas from Russia via Ukraine.

The first deliveries of natural gas via the Southern Gas Corridor are expected to start next year, as a result of the EU's consistent engagement with all the relevant partners and project stakeholders. The European Commission has also supported the efforts of eastern Mediterranean countries to explore common solutions to bring their significant gas resources to the market. There has been and there will be enough natural gas to be used as intermediate solution for our energy and heat supply so stop the promotion of cutting down forests and burning them!

About Urgenda

The Urgenda Foundation aims for a fast transition towards a sustainable society, with a focus on the transition towards a circular economy using only renewable energy. It works on solutions for this transition, including for example the introduction and realization of 'energy neutral' houses and the acceleration of electric mobility. Urgenda views climate change as one of the biggest challenges of our times and looks for solutions to ensure that the earth will continue to be a safe place to live for future generations.

www.urgenda.nl

About EDSP ECO

The EDSP ECO Foundation is a non-profit organization and provides high value consultancy and support to organizations globally that are responsible for actions to protect the planet, end poverty or grow prosperity. We work with scientists and public or private organizations to develop innovative, durable and sustainable technologies for the transition towards a circular economy and build & propose solutions to ensure that the earth will continue to be a safe place to live for future generations.
